# Introduction

The OSER is an architecture for systems designed to facilitate data processing and exchange. An OSER system instance is made up of **primary memory**, one or more **processing units** and naught or more **channel units**.

In the OSER, data processing and exchange occurs in **programs**. When a program is run, three main processes happen:

- access;
- interruption; and
- execution.

## Access

In an access, a *datum* is transferred between a unit and primary memory.

## Interruption

In an interruption, a unit causes a processing unit to run a new program.

## Execution

In execution, a processing unit runs a program.

**Part I**

**Access**

# Chapter 1

## Primary Memory

Primary memory is made of *cells*.

### Bitstrings

The cells hold **bitstrings**. In a bitstring, the bits are numbered from 1 and may take either 0 or 1 as values. A string of  $n$  bits is called an  **$n$ -string**.

Each cell in primary memory holds a single 8-string. A string longer than 8 bits is held by cutting it into 8-strings and holding the 8-strings in consecutive cells.

#### 8-String

#### 16-String

#### 32-String

#### 64-String

## 128-String

1	8 9	16 17	24 25	32
1	2	3	4	
33	40 41	48 49	56 57	64
5	6	7	8	
65	72 73	80 81	88 89	96
9	10	11	12	
97	104 105	112 113	120 121	128
13	14	15	16	

## 256-String

1	8 9	16 17	24 25	32
1	2	3	4	
33	40 41	48 49	56 57	64
5	6	7	8	
65	72 73	80 81	88 89	96
9	10	11	12	
97	104 105	112 113	120 121	128
13	14	15	16	
129	136 137	144 145	152 153	160
17	18	19	20	
161	168 169	176 177	184 185	192
21	22	23	24	
193	200 201	208 209	216 217	224
25	26	27	28	
225	232 233	240 241	248 249	256
29	30	31	32	

## Addresses

Each cell is designated by a natural number called an **address**. A bitstring longer than 8 bits is designated by the address of its first 8-string.

Each address is a **physical address** or a **virtual address**.

### Physical Address

A physical address designates a single cell in primary memory. The first cell is designated by 0, and consecutive addresses designate successive cells.

### Virtual Address

A virtual address has several formats.

#### 1st Order Format

1	7 8	16 17	25 26	34 35	43 44	52 53	64

# Chapter 2

## Units

A unit accesses the primary memory when a bitstring is transferred between this unit and designated cells.

1. The unit generates the physical address designating the first cell in primary memory.
2. The bitstring is transferred between the unit and the designated cells in primary memory.

### Physical Address

When a bitstring in primary memory is addressed, all of its constituent 8-strings are also designated.

### Transfer

The access is either a **read** or a **write**, depending on the direction of transfer.

#### Read

The access is a read when the string is sent from the unit to primary memory.

#### Write

The access is a write when the string is sent from primary memory to the unit.

### Order of Accesses

For every unit and for every primary memory cell, a read from the cell by the unit will yield the value written by the last write to that same cell by that same unit.

## Virtual Address

A virtual address is translated into a physical address.

### Frame Table

The **frame table** holds the data for address translation.

### Root Table

A root table holds 6th order frame descriptors, 6th order frame keys or 5th order frame table descriptors.

**Procedure**

The translation runs in two phases.

**Frame Table Walk**

The frame table walk yields either a frame key or a frame descriptor from a virtual address.

1. The unit reads from the root table the entry which the root index designates.
2. If the entry has none of the aforementioned formats, then condition **ZEE** happens.  
Otherwise, if the entry is either a 5th order frame key or a 5th order frame descriptor, then the unit performs the 5th order frame access with the entry.  
Otherwise, the unit reads from the 4th order frame table the entry which the 4th ring tale marcs.
3. If the entry has none of the aforementioned formats, then condition **ZEE** happens.  
Otherwise, if the entry is either a 4th order frame key or a 4th order frame descriptor, then the unit performs the 4th order frame access with the entry.  
Otherwise, the unit reads from the 3rd order frame table the entry which the 3rd ring tale marcs.
4. If the entry has none of the aforementioned formats, then condition **ZEE** happens.  
Otherwise, if the entry is either a 3rd order frame key or a 3rd order frame descriptor, then the unit performs the 3rd order frame access with the entry.  
Otherwise, the unit reads from the 2nd order frame table the entry which the 2nd ring tale marcs.

5. If the entry has none of the aforementioned formats, then condition **ZEE** happens.

Otherwise, if the entry is either a 2nd order frame key or a 2nd order frame descriptor, then the unit performs the 2nd order frame access with the entry.

Otherwise, the unit reads from the 1st order frame table the entry which the 1st ring tale marcs.

6. If the entry has none of the aforementioned formats, then condition **ZEE** happens.

Otherwise, the unit performs the 1st order frame access with the entry.

### ***n*th Order Frame Access**

The *n*th order frame access gives a physical address which is needed in step 1 of primary memory access from an *n*th order frame key or an *n*th order frame descriptor.

1. If the entry does not allow the access, then condition **ZnE** happens.

The entry allows the access if one and only one of the following conditions are met.

- The access is a write and the W-bit is 1.
- The access is a read and the R-bit is 1.
- The access is a read of a instruction (as described in step (1) of the instruction cycle) and the X-bit is 1.
- The access is a read of a root table descriptor (as described with instruction BRS) and all 3 bits are 0.

2. If the entry is a key, then the unit reads the gate to which the key's gate pointer points.
3. If the S-bit is 1, then condition **ZSW** happens.
4. If the access is a write, then the unit sets the E-bit of the entry in memory to 1.
5. The unit adds the offset to the frame pointer to give the physical address.

## **Part II**

# **Interruptions**

# Chapter 3

## Structures

In an interruption, onputs are traded between units.

### Target

A target is a processing unit.

### Gate

An interrupt gate is a cell in primary memory which is bound to a target.

### Entry

An interrupt entry holds a virtual address to data and a pointer to the root table with which the address must be translated.

T Root Table Pointer

B Data Virtual Address

### Source

A source is a unit which initiates an interruption.

## Chapter 4

# Operation

An interruption happens when the source writes an interrupt entry to the interrupt gate of the target. The target then uses the entry's virtual address to process the data.

## **Part III**

# **Execution**

# Chapter 5

## Operation

In the OSER, processing units follow a fixed operation.

### Instruction Cycle

A processing unit follows the *instruction cycle*.

1. The unit reads an instruction.
2. If the instruction is not recognized, then condition **AEA** happens.
3. The unit performs all accesses which must happen before the instruction.
4. The unit executes the instruction.
5. The unit performs all accesses which must happen after the instruction.
6. The unit starts again at (1).

### Condition

When a condition happens, the unit executes a **trap**.

A trap is a special program which gets the unit's state at the time of the condition as input.

# Chapter 6

# Processing Units

In the OSER, the processing units are built to a particular architecture.

## Register File

The processing units have a **register file** which does not depend on primary memory.

## Data

Data can be either a fixed point number or a floating point number.

### Fixed Point Numbers

Let  $Z_U(S, M)$  be the number expressed by a bitstring  $S$  with lowest power  $M$  in an unsigned interpretation.

$$Z_U(S, M) = 2^M \sum_{i=1}^{|S|} 2^{|S|-i} S_i$$

Let  $Z_Z(S, M)$  be the number expressed by a bitstring  $S$  with lowest power  $M$  in a signed interpretation.

$$Z_Z(S, M) = 2^M \left( -2^{|S|-1} S_1 + \sum_{i=2}^{|S|} 2^{|S|-i} S_i \right)$$

## Floating Point Numbers

Let  $X(V, M, B)$  be the number expressed by a sign bit  $V$ , an exponent bitstring  $M$  and a fraction bitstring  $B$ .

$$X(V, M, B) = (-1)^V 2^{Z_U(M, 0) - 2^{|M|-1}} Z_U(B, -1 - |B|)$$

#### X4

**X8****X16****X32**

## Instructions

A instruction describes a change in the program's state. Each instruction has various **formats**.

### Control Instruction

A control instruction changes the run of the program when its condition is fulfilled. Each bit of the instruction condition designates a value of the SR-condition field, and the instruction condition is fulfilled if the SR-condition has a value whose bit in the instruction's condition is 1.

A control instruction has three formats.

**Constant Format**

In this format:

- the target is register  $R$ ;
- the source is  $W$ .

**Memory Format**

In this format:

- the target is register  $R$ ;
- the source is the primary memory at the address given by the sum of  $A$  and register  $Q$ .

**Register Format**

In this format, the target and source are registers  $R$  and  $Q$ .

**SCI – Scip**

After this instruction:

- $IP$  is the sum of  $IP$  and the source;
- the target is  $IP$  before the instruction.

**JMP – Jump**

After this instruction:

- $IP$  is the source;
- the target is  $IP$  before the instruction.

**Move Instruction**

A move instruction describes a movement of data between primary memory and the register file.

**STR – Stir**

After this instruction, the target is set to the source.

This instruction has four formats.

**Constant Format**

In this format:

- the target is register  $Z$ ;
- the source is  $W$ .

**Memory Format**

In this format:

- the target is register  $Z$ ;
- if the Ä-bit is 0, then the source is the primary memory at the address given by the sum of  $A$  and register  $Q$ ;  
otherwise:
  - the source is the primary memory cell which register  $Q$  designates;
  - $A$  is added to register  $Q$  after the instruction.

In this format:

- if the Ä-bit is 0, then the target is the primary memory at the address given by the sum of  $A$  and register  $Z$ ;  
otherwise:

- $A$  is added to register  $Z$  before the instruction;
- the target is the primary memory at the address in register  $Z$ ;
- the source is register  $Q$ .

**Near hold format**

1	8	9	12	13	16
1	1	1	0	0	0
Z			Q		

In this format, the target and source are registers  $Z$  and  $Q$ .

**USS – Unsplit Stir**

This instruction's execution depends on its format.

This instruction has two formats.

1	8	9	12	13	16	17	18	20	21	32
0	1	1	0	0	0	1	Z	Q	0	G
A										

In this format:

- the target is register  $Z$ ;
- the source is the primary memory at the address given by the sum of  $A$  and register  $Q$ .

1	8	9	12	13	16	17	18	20	21	32
1	0	1	1	0	0	0	1	Z	Q	0
G										
A										

In this format:

- the target is the primary memory at the address given by the sum of  $A$  and register  $Z$ ;
- the source is register  $Q$ .

In particular, this instruction will trap if a write to the target has happened after the last **USS** thereto.

**BRS – Brooc Switch**

This instruction's run depends on its format.

This instruction has two formats.

1	8	9	12	13	16	17	32
0	1	1	0	0	1	0	R
Q		A					

In this format:

- $SR$  is put in primary memory at the address in register  $R$ ;
- a new status register is loaded from primary memory at the address given by the sum of  $A$  and register  $Q$ .

1	8	9	12	13	16
1	1	1	0	0	1
R			Q		

In this format:

- $SR$  is put in primary memory at the address in register  $R$ ;
- a new status register is loaded from primary memory at the address given by the sum of  $A$  and register  $Q$ .

**Bitwise Instruction**

A bitwise instruction describes a calculation over individual bits.

Each bitwise instruction has four formats.

**Constant Format**

1	4	5	8	9	12	13	32
0	0	1	0	*	*	*	*
Z				W			

In this format:

- the target is register  $Z$ ;

**THR – Thraw**

After this instruction, the target is rotated to the right by the number of bits given by the source.

**AND – Throughcut**

After this instruction, each of the target's bits will be set to the conjunction of the matching bits of the target and the source.

**OR – Foronening**

After this instruction, each of the target's bits will be set to the union of the matching bits of the target and the source.

**NOT – Not**

After this instruction, each of the target's bits will be set to the complement of the matching bits of the source.

**SSW – Sign Swap**

After this instruction, the target will be set to the negative of the source.

In the costant format, the source is zero-extended.

**Arithmetic Instruction**

An arithmetic instruction describes an arithmetic calculation.

All arithmetic instructions calculate over fixed point numbers.

Each arithmetic instruction has four formats.

**Constant Format**

In this format:

- the target is register Z;

**CUT – Fordeal**

After this instruction, the source is divided by the target.

In the constant format, the source is sign-extended.
